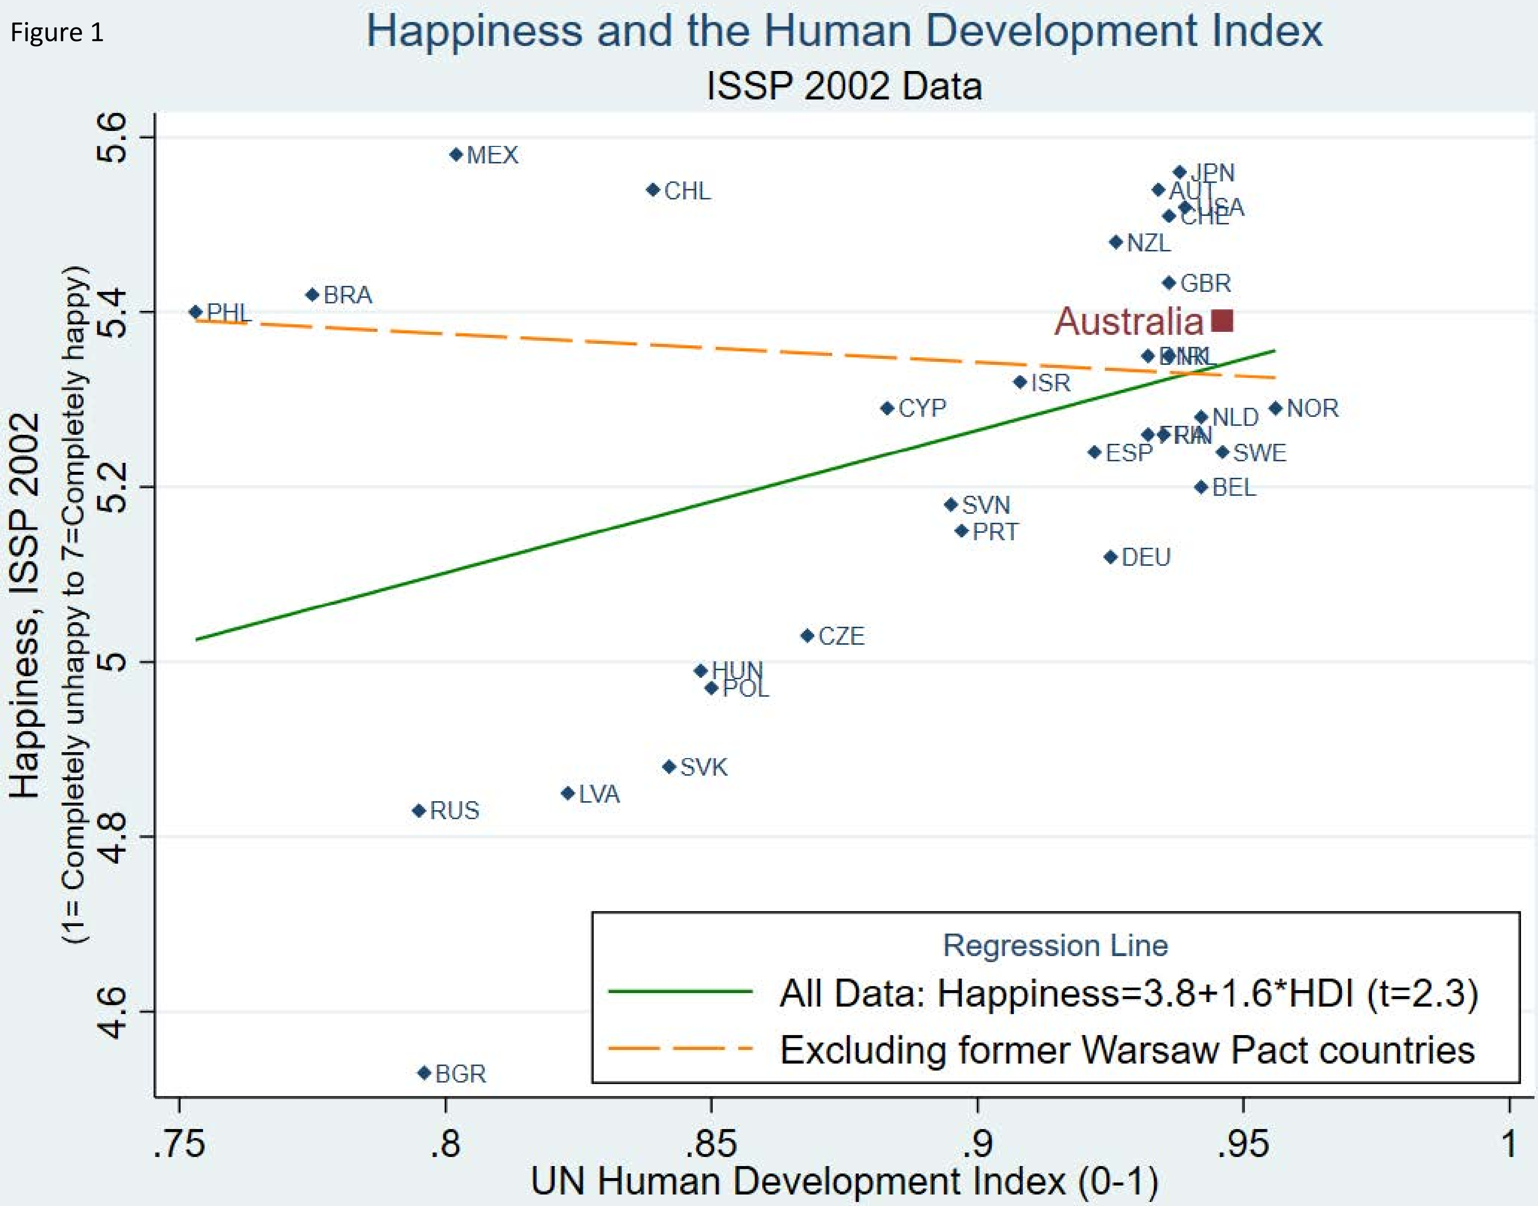
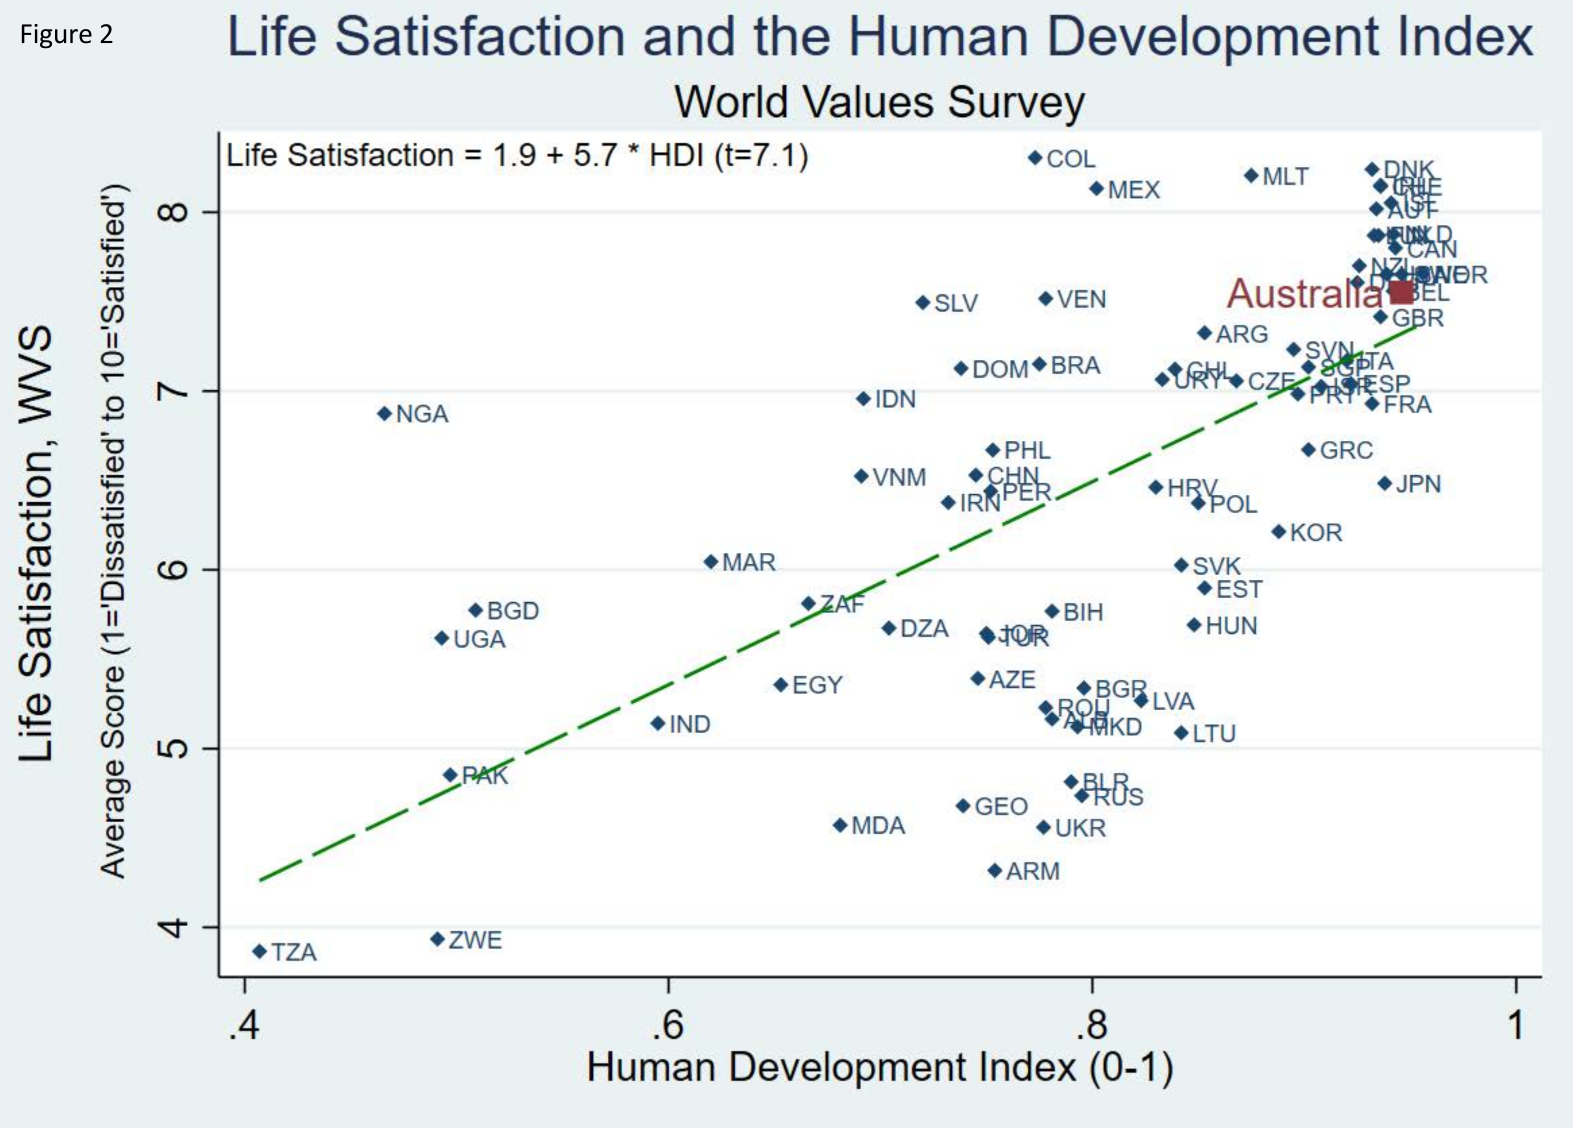
Figure 1



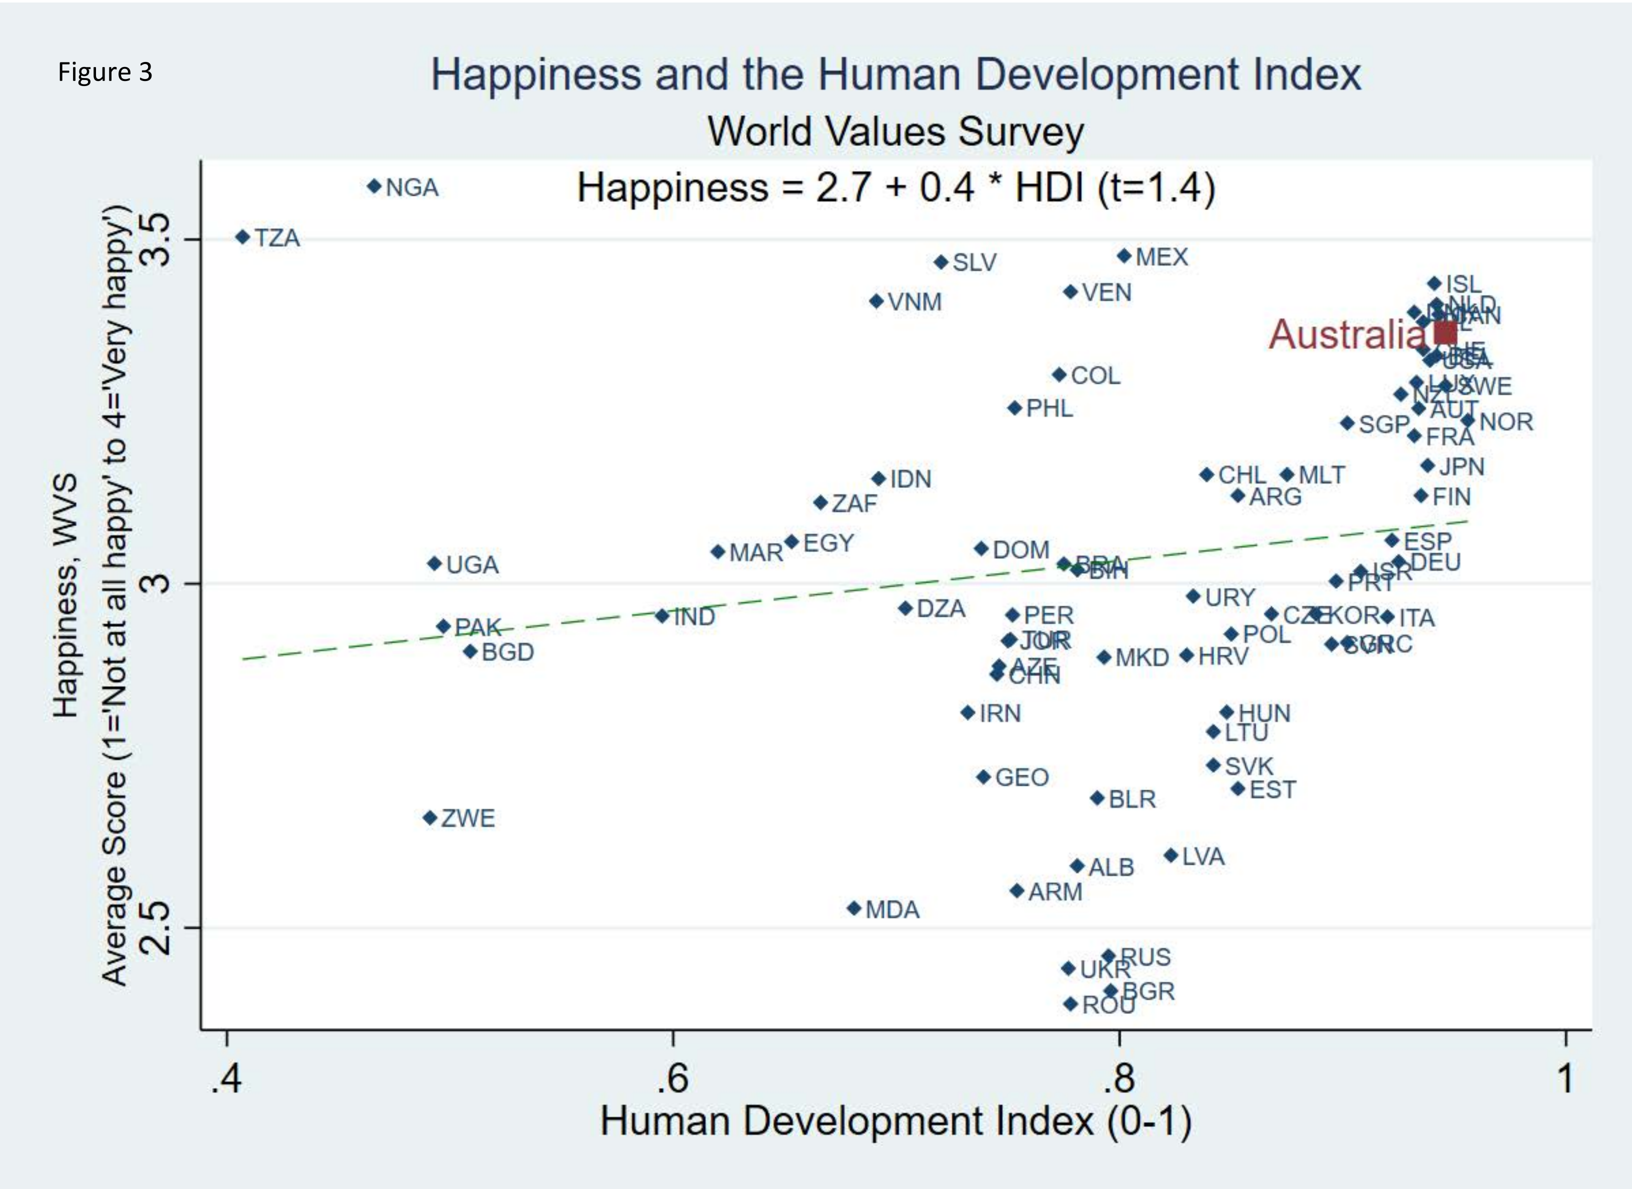
1. The relevant country group would be the countries with HDI levels around 0.9 and 0.95. The green regression line predicts Australia’s happiness level to be lower. And there are plenty of countries with near HDI levels of the Australia’s that are corresponding with lower happiness levels. So, it does not seem that there is a paradox. And Australia is happier than the prediction. After excluding the former Warsaw Pact countries, the slope of the regression line changes. And it seems as the lower HDI levels corresponds to more happiness.

Figure 2



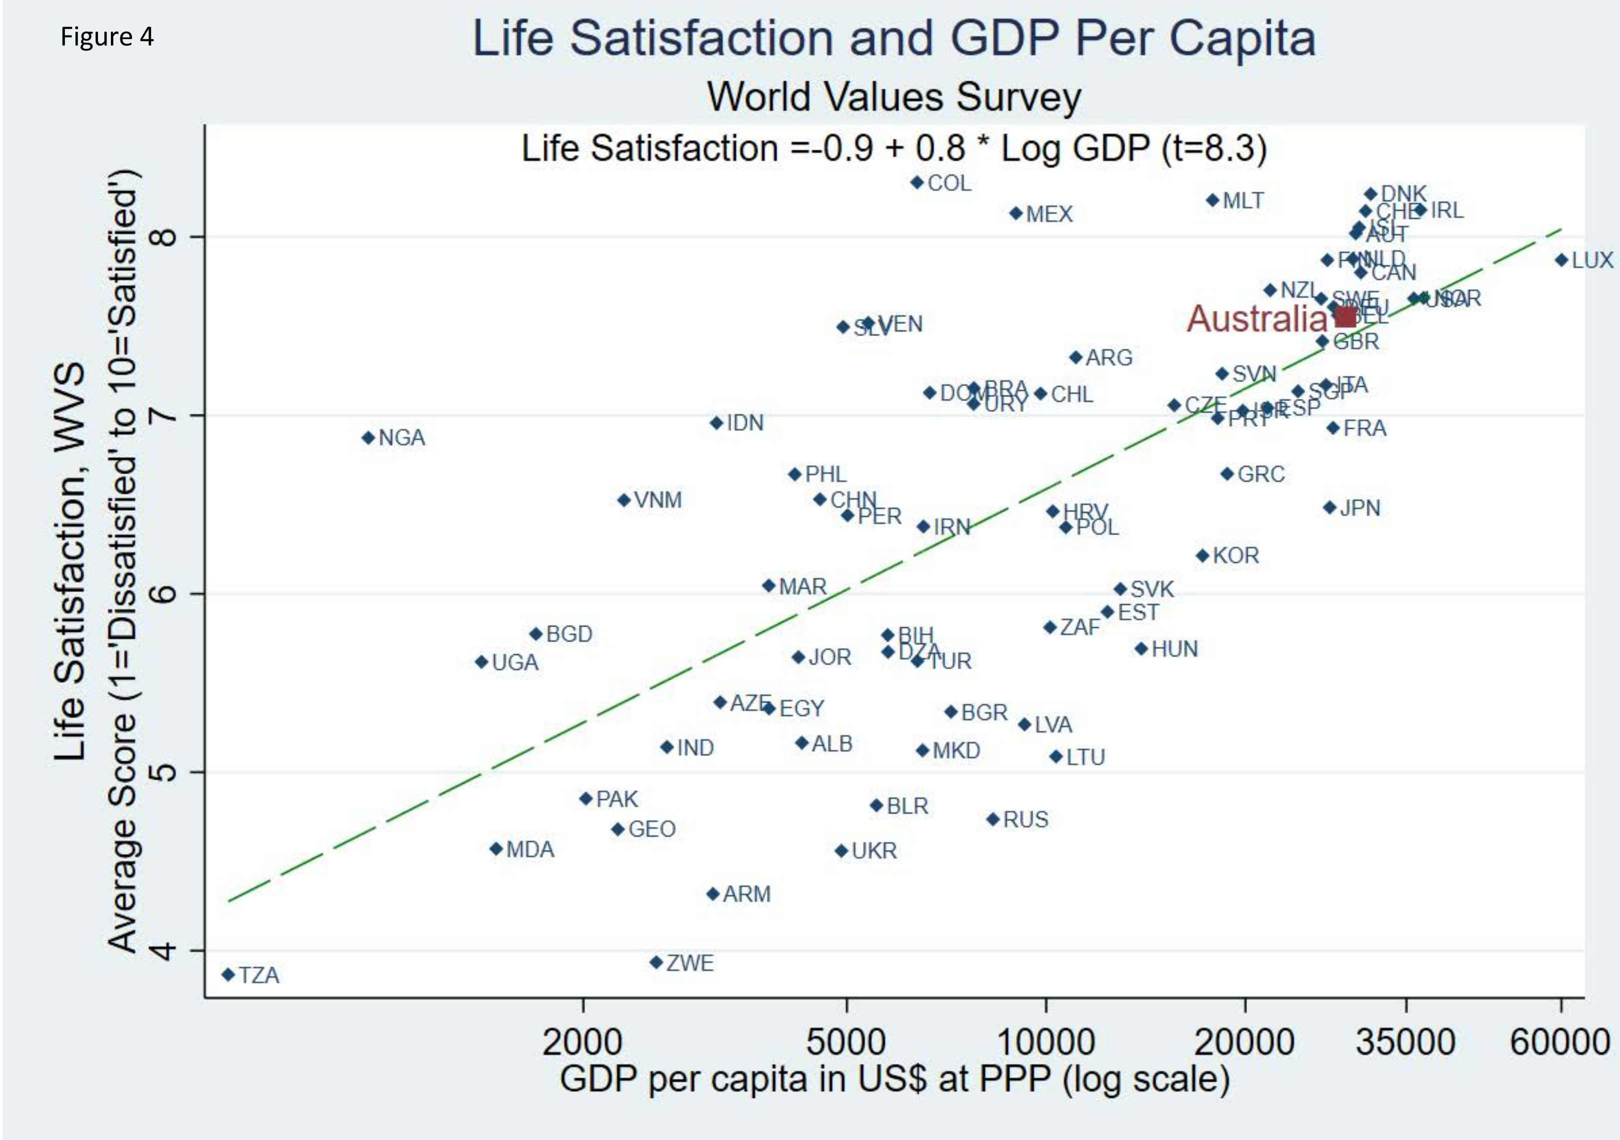
2. The correlation coefficient is 0.6352, means that there is moderate positive linear relationship. There is not really a strong or a weak correlation. It can be also seen visually in graph by the distribution of the points and the slope.

Figure 3



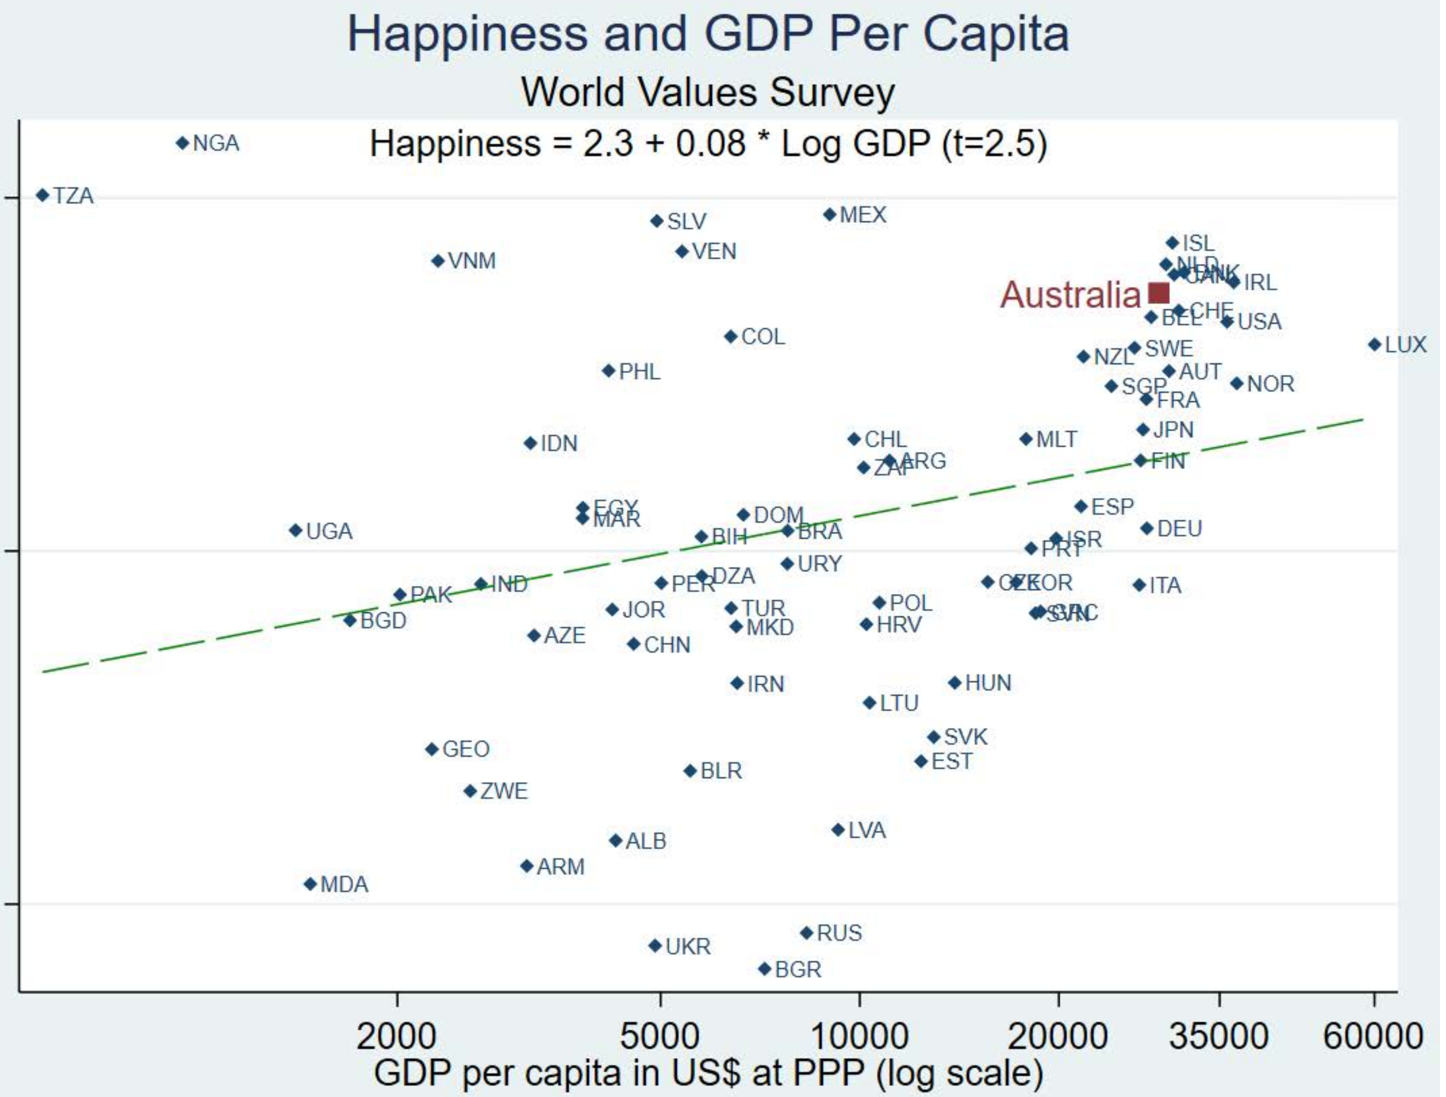
3. I don't think that there is a big difference on figures, considering that the most of the countries stand on near positions by the regression line. It should be considered that the x and y axes have different ranges on both graphs. Figure 3 has more observations and a regression line with lower t-value. Means it could be more to be rely on. I think there is some distinction between the happiness and the life satisfaction, because there are some countries with different results on both figures, but I don't think the distinction is really high, they gave similar results overall. Tanzania and Nigeria are drawing attention with low HDI levels and highest happiness levels. And there is the "Warsaw quadruple" Ukraine, Russia, Romania and Bulgaria.

Figure 4



4. There is a positive moderate correlation between the life satisfaction and the GDP. GDP accords with the "lifesat" in a similar way as the HDI accords. Regression lines and country dots demonstrate similar positions.

Figure 5



5. There is a weak positive correlation between the happines and the GDP. GDP accords with the "happins" in a similar way as the HDI accords. Regression lines and country dots demonstrate similar positions.

6. All graphs demonstrate the Australia as they are happier than the regression line. Australia do not seem to be relatively unhappy, they are relatively happy. Their all happiness scores accord with the other countries that are showing similar scores on both HDI and GDP measurements. And I do not find the relationship between subjective well-being and development in Australia puzzling. The real question would be the Norway's position, they are ahead in both GDP and HDI scores but they have quite lower happiness levels. Australia at least is always above the regression lines.
